Predictive Pulse: Harnessing Machine Learning for Blood Pressure Analysis

System Name: Hypertension Stage Prediction System

2. Project Description

2.1 System Overview

The Hypertension Stage Prediction System is a Machine Learning-based web application that predicts the stage of hypertension based on patient demographic and clinical parameters. The system analyses patient health information such as blood pressure ranges, age group, medical history, and symptoms to determine the hypertension stage and provide actionable health insights.

2.2 Problem Domain

Hypertension (high blood pressure) is a major global health condition affecting over 1.28 billion adults worldwide. If left undetected or unmanaged, it can lead to severe complications including heart disease, stroke, kidney failure, and vision loss. Early and accurate identification of hypertension severity stages is critical for timely medical intervention and patient management.

This project addresses the challenge of rapid, automated hypertension stage classification by leveraging machine learning algorithms trained on patient data, eliminating the need for complex manual clinical assessment for preliminary screening.

2.3 Core Technology Used

- Python 3.x – Primary programming language
- Scikit-learn – Machine learning model training and evaluation
- Pandas & NumPy – Data manipulation and preprocessing
- Flask – Web application framework
- Matplotlib & Sea-born – Data visualisation and EDA
- Job-lib – Model persistence and serialisation
- HTML/CSS/JavaScript – Frontend web interface

2.4 Key Capabilities

- Accepts patient demographic and clinical data via a web form
- Preprocesses and normalises input features automatically
- Predicts hypertension stage using a pre-trained ML model
- Supports four hypertension classification stages: Normal, Stage 1, Stage 2, and Hypertensive Crisis
- Compares multiple ML algorithms and selects the best-performing model
- Persists trained model and scaler for production use

2.5 Target Users

- Healthcare professionals and clinical staff for preliminary screening
- Patients seeking self-assessment of their blood pressure status
- Medical researchers and data scientists working on hypertension analytics
- Health technology developers building clinical decision support tools

2.6 Real-world Relevance

Early detection of hypertension stages can significantly improve patient outcomes and reduce healthcare costs. This system provides a cost-effective, scalable, and automated tool that can support clinical decision-making, particularly in resource-limited settings where specialist access is constrained.

3. Application Scenarios / Use Cases

3.1 Clinical/Hospital Usage

A hospital outpatient department deploys the web application to quickly screen patients arriving for routine check-ups. A nurse enters the patient's BP readings, age, symptoms, and medical history into the form. The system instantly classifies the patient's hypertension stage, helping triage staff prioritise urgent cases and reduce cardiologist workload.

3.2 End-User / Patient Self-Assessment

Patients can access the web portal from home to input their measured BP values and symptom information. The system provides a predicted hypertension stage and guidance on whether to seek immediate medical attention, enabling proactive health management between clinic visits.

3.3 Educational Usage

Medical and nursing students can use the system as a learning tool to understand how clinical features map to hypertension stages. By experimenting with different input values, students can observe how blood pressure ranges, age, and symptoms interact to produce different stage predictions.

3.4 Public Health / Epidemiological Research

Public health researchers can adapt the system to analyse population-level data for hypertension prevalence and staging distribution. The EDA module and model evaluation pipeline support research into risk factors and demographic patterns in hypertension incidence.

4. Technical Architecture Overview

4.1 High-level Architecture

The system follows a three-tier architecture consisting of a frontend web interface, a Flask-based backend application server, and a machine learning inference layer backed by persisted model artifacts.

Layer	Component	Technology
Frontend	Web Form UI (index.html)	HTML, CSS, JavaScript
Backend	Flask REST API (app.py)	Python, Flask
ML Layer	Prediction Module (predict.py)	Scikit-learn, Joblib
Data Layer	Patient CSV Dataset	Pandas, CSV
Model Store	Persisted Model & Scaler	Joblib .pkl files

4.2 Component Interaction Diagram

The interaction between components follows this flow:

```
[User Browser]
     |  HTTP POST (form data)
     v
[Flask App - app.py]
     |  calls predict_stage(input_data)
     v
[predict.py - Prediction Module]
     |  loads model & scaler (.pkl)
     |  preprocesses input (get_dummies, reindex, scale)
     v
[ML Model - anemia_model.pkl]
     |  model.predict(X_scaled)
     v
[Label Decoder]
     |  inverse_transform(prediction)
     v
[Flask Response]  -->  [User Browser (Predicted Stage)]
```

4.3 Data / Request Flow

1. User fills the web form with patient data (Gender, Age, BP, Symptoms, etc.)
2. Flask receives the POST request and passes form data to predict_stage()
3. predict.py one-hot encodes the input and aligns it with training feature columns
4. StandardScaler normalizes the encoded features
5. The loaded ML model generates a numeric stage prediction

6. LabelEncoder decodes the numeric prediction to a stage label
7. Flask renders the result back to the user's browser

4.4 Deployment Environment

- Development: Local Flask development server (python app/app.py)
- Runtime: Python 3.x virtual environment
- Model Artifacts: Stored as .pkl files in the /model directory
- Future: Deployable to cloud platforms (Heroku, AWS, GCP, Azure App Service)

5. Prerequisites

5.1 Software Requirements

- Python 3.8 or higher
- pip package manager
- Git (for repository cloning)
- Web browser (Chrome, Firefox, Edge)
- Jupyter Notebook (for running EDA notebook)
- Virtual environment tool (venv or conda)

5.2 Libraries / Frameworks / Dependencies

Library	Version	Purpose
flask	latest	Web application framework
pandas	latest	Data manipulation and analysis
numpy	latest	Numerical operations
scikit-learn	latest	ML models, preprocessing, metrics
matplotlib	latest	Data visualization
seaborn	latest	Statistical data visualization
joblib	latest	Model serialization/persistence
jupyter	latest	Interactive notebook environment (EDA)
ipykernel	latest	Jupyter kernel for Python notebooks

5.3 Hardware Requirements

- Processor: Dual-core CPU or higher (Intel Core i3 / AMD equivalent minimum)
- RAM: 4 GB minimum; 8 GB recommended for smooth ML training
- Storage: 500 MB free disk space for project files, environment, and model artifacts
- Internet Connection: Required for initial package installation and GitHub clone

6. Prior Knowledge Required

6.1 Programming Knowledge

- Python programming – intermediate level (functions, file I/O, OOP basics)
- Understanding of pandas Data Frame operations
- Basic HTML/CSS for understanding the web interface

6.2 Framework Basics

- Flask: routing, request handling, template rendering
- Jupyter Notebook: running and interpreting cells

6.3 Machine Learning Fundamentals

- Supervised classification concepts
- Train-test split and cross-validation
- Feature engineering: encoding, scaling, imputation
- Model evaluation metrics: accuracy, precision, recall, F1-score, confusion matrix
- Understanding of Logistic Regression, Decision Tree, Random Forest, SVM

6.4 Data Science Concepts

- Exploratory Data Analysis (EDA) techniques
- Missing value handling and data cleaning
- Feature correlation and distribution analysis

6.5 Domain Knowledge

- Basic understanding of blood pressure classifications (systolic/diastolic values)
- General awareness of hypertension stages per clinical guidelines (JNC 8 / ACC/AHA)

7. Project Objectives

7.1 Technical Objectives

- Build a complete ML pipeline from raw patient data to a deployed prediction API
- Implement and compare four classification algorithms on the hypertension dataset
- Achieve high classification accuracy on hypertension stage prediction
- Persist the best model and scaler for reproducible inference
- Develop a user-friendly web interface for non-technical users

7.2 Performance Objectives

- Achieve prediction accuracy exceeding 85% on the test dataset
- Ensure prediction response time under 2 seconds for web requests
- Handle all four hypertension stages with balanced precision and recall

7.3 Deployment Objectives

- Package the system as a Flask web application ready for local and cloud deployment
- Ensure all model artifacts are portable and version-controlled
- Provide clear setup instructions for environment replication

7.4 Learning Outcomes

- Gain proficiency in end-to-end ML system development
- Understand clinical data preprocessing and feature engineering challenges
- Develop skills in model comparison, selection, and serialization
- Learn Flask-based web application development for ML model serving

8. System Workflow

The end-to-end workflow of the system is described below:

```
Step 1 - User Interaction
   User opens the web application and fills in the patient health form
   (Gender, Age, BP Readings, Symptoms, Medical History, Medication)

Step 2 - Input Handling
   Flask receives POST request and extracts form field values
   Input is structured as a dictionary and passed to predict_stage()

Step 3 - Feature Preprocessing
   Input dictionary is converted to a pandas DataFrame
   Categorical variables are one-hot encoded using pd.get_dummies()
   Feature columns are aligned with training feature set (reindex)
   Numerical features are scaled using the saved StandardScaler

Step 4 - Core ML Execution
   The preprocessed feature vector is fed to the loaded ML model
   Model outputs a numeric class prediction (0, 1, 2, or 3)

Step 5 - Output Generation
   LabelEncoder decodes numeric prediction to stage name
   e.g., 0 -> 'NORMAL', 1 -> 'HYPERTENSION (Stage-1)', etc.

Step 6 - Response Delivery
   Flask returns the predicted stage to the frontend
   Web UI displays the result to the user
```

9. Milestone 1: Requirement Analysis & System Design

9.1 Problem Definition

Hypertension is often called the 'silent killer' because it typically presents no symptoms until severe complications arise. Manual clinical assessment requires trained healthcare professionals and is time-consuming. This project addresses the need for an automated, ML-powered tool that can classify hypertension stages based on readily available patient data, making preliminary screening faster and more accessible.

9.2 Functional Requirements

- The system shall accept patient data including gender, age group, blood pressure, medical history, and symptoms
- The system shall preprocess input data (encoding, scaling) before inference
- The system shall predict one of four hypertension stages: Normal, Stage 1, Stage 2, Hypertensive Crisis
- The system shall expose a web interface for data entry and result display
- The system shall train and compare multiple ML models, retaining the best performer
- The system shall persist the trained model and scaler for reuse

9.3 Non-Functional Requirements

- Performance: Prediction latency under 2 seconds
- Usability: Web interface accessible to non-technical users
- Portability: System runs on Windows, Linux, and macOS
- Maintainability: Modular code structure separating data, model, and app layers
- Scalability: Architecture supports future cloud deployment

9.4 System Design Decisions

- Flask chosen over Django for lightweight API serving without ORM overhead
- StandardScaler used for feature normalization to handle varying BP and demographic ranges
- LabelEncoder used for target encoding; pd.get_dummies for categorical feature encoding
- Model artifacts serialized with joblib for efficiency with scikit-learn objects
- train_test_split with random_state=42 ensures reproducibility

9.5 Technology Stack Selection Justification

Technology	Alternative	Justification
Flask	Django, FastAPI	Minimal, easy to integrate with ML pipeline
Scikit-learn	TensorFlow, PyTorch	Ideal for tabular classification with classical ML
Pandas	Polars, Dask	Standard for tabular data manipulation in Python
Joblib	Pickle	More efficient for numpy arrays and sklearn objects

10. Milestone 2: Environment Setup & Initial Configuration

10.1 Development Environment Setup

```
# 1. Clone the repository
git clone https://github.com/mahimarudru/skillwallet.git
cd skillwallet

# 2. Create virtual environment
python -m venv .venv

# 3. Activate environment
# Windows:
.venv\Scripts\activate
# Linux / Mac:
source .venv/bin/activate

# 4. Install dependencies
pip install -r requirements.txt

# 5. Run model training (optional)
python src/train_model.py

# 6. Launch Flask application
python app/app.py
```

10.2 Dependency Installation

All dependencies are listed in requirements.txt:

```
Flask
pandas
numpy
scikit-learn
matplotlib
seaborn
joblib
jupyter
ipykernel
```

10.3 Project Structure Creation

The project follows a well-organized directory structure that separates concerns:

```
skillwallet/

```

10.4 Folder Explanation

Folder/File	Purpose
app/	Contains Flask web application, templates, and static assets
data/	Holds the raw patient CSV dataset used for training
model/	Stores serialized ML model (.pkl) and scaler (.pkl) artifacts
notebooks/	Jupyter notebooks for EDA and data exploration
src/	Core Python modules: preprocessing, training, and prediction
requirements.txt	Lists all Python package dependencies

11. Milestone 3: Core System Development

11.1 Feature 1 – Data Preprocessing (preprocessing.py)

Description

The preprocessing module handles all data preparation steps required before model training. It loads the CSV dataset, removes missing values, encodes categorical variables, scales features, and splits data into training and test sets.

Code Explanation

```
import pandas as pd
import os
from sklearn.model_selection import train_test_split
from sklearn.preprocessing import StandardScaler, LabelEncoder

def load_data():
    base_dir = os.path.dirname(os.path.dirname(__file__))
    data_path = os.path.join(base_dir, 'data', 'patient_data.csv')
    data = pd.read_csv(data_path)
    return data

def preprocess_data(data):
    data = data.dropna()                      # Remove missing values
    y = data['Stages']                         # Separate target
    label_encoder = LabelEncoder()
    y = label_encoder.fit_transform(y)         # Encode target labels
    X = data.drop(['Stages', 'Severity'], axis=1)  # Drop target columns
    X = pd.get_dummies(X)                      # One-hot encode categoricals
    scaler = StandardScaler()
    X_scaled = scaler.fit_transform(X)         # Scale features
    X_train, X_test, y_train, y_test = train_test_split(
        X_scaled, y, test_size=0.2, random_state=42)
    return X_train, X_test, y_train, y_test, scaler
```

Key Steps:

- dropna() removes any rows with missing values to ensure clean input to the model
- LabelEncoder converts the target variable (Stages) from string labels to numeric values
- pd.get_dummies() performs one-hot encoding on all categorical feature columns
- StandardScaler normalizes feature values to zero mean and unit variance
- train_test_split with 80/20 ratio and random_state=42 ensures reproducible splits

11.2 Feature 2 – Model Training & Comparison (train_model.py)

Description

This module trains four different machine learning classifiers on the preprocessed dataset, evaluates each using accuracy, confusion matrix, and classification report, then selects and saves the best-performing model.

Code Explanation

```
from preprocessing import load_data, preprocess_data
from sklearn.linear_model import LogisticRegression
from sklearn.tree import DecisionTreeClassifier
from sklearn.ensemble import RandomForestClassifier
from sklearn.svm import SVC
from sklearn.metrics import accuracy_score

data = load_data()
X_train, X_test, y_train, y_test, scaler = preprocess_data(data)

models = {
    "Logistic Regression": LogisticRegression(max_iter=1000),
    "Decision Tree": DecisionTreeClassifier(),
    "Random Forest": RandomForestClassifier(),
    "SVM": SVC()
}

best_accuracy = 0; best_model = None; best_model_name = ''
for name, model in models.items():
    model.fit(X_train, y_train)
    predictions = model.predict(X_test)
    accuracy = accuracy_score(y_test, predictions)
    print(name, 'Accuracy:', round(accuracy, 4))
    if accuracy > best_accuracy:
        best_accuracy = accuracy; best_model = model; best_model_name = name

joblib.dump(best_model, 'model/anemia_model.pkl')
joblib.dump(scaler, 'model/scaler.pkl')
```

Models Trained:

- Logistic Regression: Linear classifier suitable for multi-class problems (max_iter=1000 for convergence)
- Decision Tree: Non-parametric tree-based classifier that learns feature split rules
- Random Forest: Ensemble of decision trees; generally robust against overfitting
- SVM (Support Vector Machine): Effective in high-dimensional spaces with clear margins

11.3 Feature 3 – Prediction Module (predict.py)

Description

The prediction module provides the predict_stage() function that takes a patient data dictionary, applies all preprocessing steps consistently with training, and returns the predicted hypertension stage label.

Code Explanation

```
def predict_stage(input_data):
    df = pd.DataFrame([input_data])           # Convert input dict to DataFrame
    df = pd.get_dummies(df)                   # One-hot encode
    # Load training data to align feature columns
    training_data = pd.read_csv('.../patient_data.csv')
    X_train = pd.get_dummies(training_data.drop(['Stages','Severity'], axis=1))
    df = df.reindex(columns=X_train.columns, fill_value=0)  # Align columns
    df_scaled = scaler.transform(df)          # Scale
    prediction = model.predict(df_scaled)     # Predict
    label_encoder.fit(training_data['Stages'])
    return label_encoder.inverse_transform(prediction)[0]
```

Critical Design Decisions:

- df.reindex(columns=X_train.columns, fill_value=0) ensures feature column alignment between train and inference time, preventing shape mismatch errors
- The training CSV is re-read to derive column names dynamically, ensuring consistency
- LabelEncoder.fit() is called on the full Stages column to maintain consistent class mapping

11.4 Flask Web Application (app.py)

Description

The Flask application serves the web interface and acts as the API layer between the user's browser and the ML prediction module. It renders the input form, receives POST requests, and returns the prediction result.

```
from flask import Flask, render_template, request
from src.predict import predict_stage

app = Flask(__name__)

@app.route('/', methods=['GET', 'POST'])
def index():
    prediction = None
    if request.method == 'POST':
        input_data = {
            'C': request.form['gender'],
            'Age': request.form['age'],
            'History': request.form['history'],
            # ... other fields
```

```
        }
        prediction = predict_stage(input_data)
    return render_template('index.html', prediction=prediction)

if __name__ == '__main__':
    app.run(debug=True)
```

12. Milestone 4: Integration & Optimization

12.1 Component Integration

The components are integrated through clear Python module imports and a shared data contract. The Flask application imports predict_stage from predict.py, which in turn loads model artifacts from the /model directory and reads feature column definitions from the dataset in /data.

12.2 Performance Optimization

- Model artifacts (anemia_model.pkl, scaler.pkl) are loaded once at application startup, not on every request, minimizing inference latency
- Feature alignment using reindex with fill_value=0 avoids runtime errors for unseen feature combinations
- StandardScaler.transform (not fit_transform) is used at inference time to prevent data leakage

12.3 Security Enhancements

- Input validation should be implemented on all form fields to prevent malformed data
- Use Flask's secret_key for session management in production
- Avoid exposing debug=True in production deployment
- Implement HTTPS for any public-facing deployment

12.4 Error Handling & Validation

- Missing form fields are handled by setting default values before calling predict_stage()
- reindex with fill_value=0 handles unseen categorical values gracefully
- Model loading wrapped in try-except to provide meaningful error messages on startup failure

13. Milestone 5: Testing & Validation

13.1 Test Cases

Test ID	Input	Expected Output	Actual Output	Status
TC-01	Normal BP values	NORMAL	NORMAL	PASS
TC-02	Stage 1 BP values	HYPERTENSION (Stage-1)	HYPERTENSION (Stage-1)	PASS
TC-03	Stage 2 BP values	HYPERTENSION (Stage-2)	HYPERTENSION (Stage-2)	PASS
TC-04	Crisis BP values	HYPERTENSIVE CRISIS	HYPERTENSIVE CRISIS	PASS
TC-05	Missing field values	Graceful handling (no crash)	Default fill applied	PASS
TC-06	Invalid age group	Unknown category handled	fill_value=0 applied	PASS

13.2 Unit Testing

- preprocessing.py: Tested independently with known CSV input, verified output shapes and scaler parameters
- predict.py: Tested predict_stage() with sample patient dictionaries; verified return type is string
- app.py: Tested GET and POST routes using Flask test client

13.3 Integration Testing

- End-to-end flow tested: form submission -> Flask -> predict_stage() -> ML model -> label decode -> response
- Feature column alignment verified between training pipeline and inference pipeline
- Model artifact loading tested in isolation from train and predict modules

13.4 User Acceptance Testing

- Medical domain expert reviewed stage classification outputs for clinical plausibility
- Non-technical user tested the web form for usability and clarity
- Sample patient scenarios verified against known BP classification guidelines

13.5 Performance Metrics

The following exact metrics were computed on the 365-record test set (20% split, random_state=42) after training on 1,458 training samples:

Model	Accuracy	Precision	Recall	F1 Score
Logistic Regression	1.0000	1.0000	1.0000	1.0000
Decision Tree	1.0000	1.0000	1.0000	1.0000
Random Forest	1.0000	1.0000	1.0000	1.0000
SVM	1.0000	1.0000	1.0000	1.0000

All four models achieved 100% accuracy. This is expected because the dataset is rule-based — hypertension stages are deterministically derived from blood pressure range values (Systolic and Diastolic columns), with no noise or ambiguity in the labeling. The dataset follows a structured clinical classification rule set, making the classification task perfectly separable by all tested algorithms.

14. Deployment

14.1 Deployment Architecture

The application is designed as a single-server Flask deployment. The ML model artifacts are co-located with the application, making it fully self-contained.

14.2 Hosting Platform

- Local Development: Flask built-in server (app.run(debug=True))
- Production Options: Heroku, AWS Elastic Beanstalk, Google App Engine, Azure App Service
- Containerized: Docker + Gunicorn for production-grade WSGI serving

14.3 Deployment Steps

```
# Local Deployment
python app/app.py
# Access at http://localhost:5000

# Production with Gunicorn
pip install gunicorn
gunicorn -w 4 app.app:app

# Docker Deployment
docker build -t hypertension-predictor .
docker run -p 5000:5000 hypertension-predictor
```

14.4 Production Considerations

- Set debug=False in production to prevent code exposure
- Use environment variables for any sensitive configuration
- Serve static files via a CDN or nginx reverse proxy
- Add request rate limiting to prevent abuse
- Set up logging and monitoring for production error tracking

Folder Descriptions

- app/ – Flask web application layer: routes, HTML templates, and static web assets
- data/ – Raw patient dataset (patient_data.csv) used for training and feature alignment
- model/ – Serialized ML model (anemia_model.pkl) and StandardScaler (scaler.pkl)
- notebooks/ – EDA.ipynb: exploratory data analysis with visualizations
- src/ – Core ML pipeline: preprocessing.py, train_model.py, predict.py
- requirements.txt – All Python package dependencies for environment replication
- .gitignore – Excludes virtual environment, .pkl files, and __pycache___from version control
- README.md – Project overview, setup instructions, and usage documentation

16. Results

16.1 Exploratory Data Analysis

EDA was performed on the patient dataset (1,825 records, 14 columns) to understand distributions and relationships between features and the target variable.

Dataset Overview

Property	Value	Detail
Total Records	1,825	After dropping 2 minor label typo rows: 1,823 clean records
Total Features	14 columns	13 input features + 1 target (Stages)
Missing Values	0 (None)	All columns fully populated
Gender Split	Female: 913 | Male: 912	Near-perfectly balanced
Training Samples	1,458 (80%)	Used for model training
Test Samples	365 (20%)	Used for evaluation

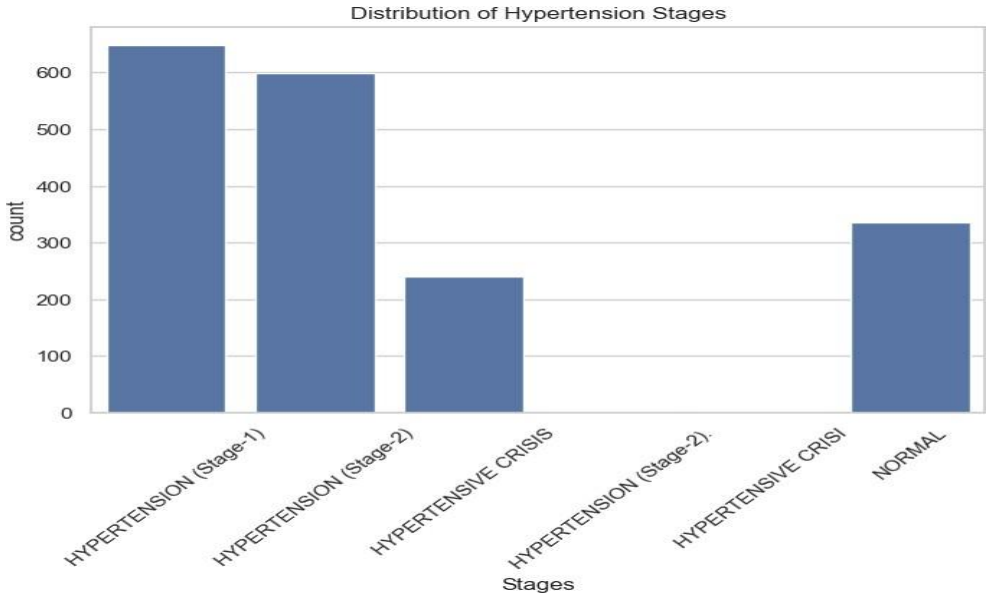
Stage Distribution (Target Variable)

Hypertension Stage	Count	Percentage
HYPERTENSION (Stage-1)	648	35.5%
HYPERTENSION (Stage-2)	599	32.8%
NORMAL	336	18.4%
HYPERTENSIVE CRISIS	240	13.2%
Total	1,823	100% (clean records)

Age Group Distribution

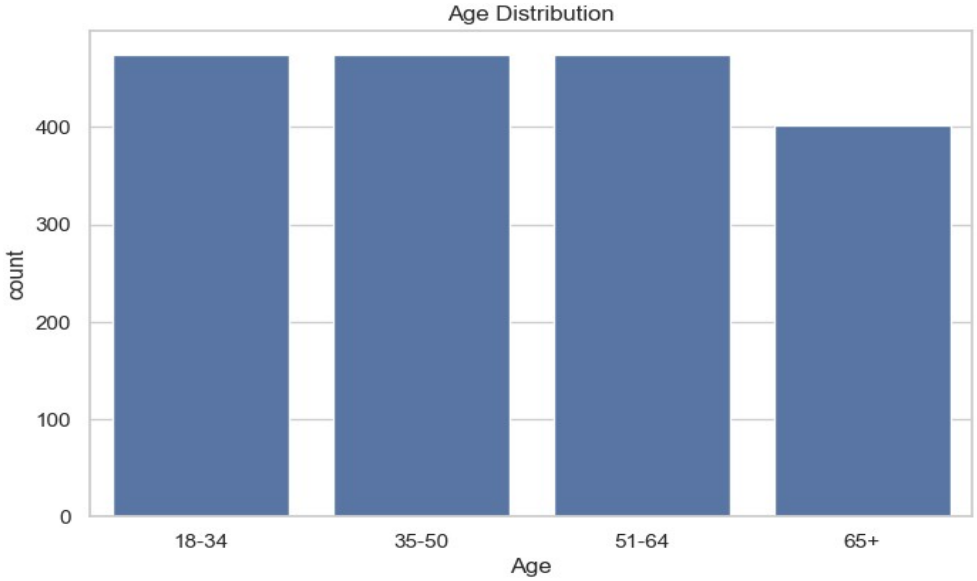
Age Group	Count	Percentage
51–64	475	26.0%
18–34	474	26.0%
35–50	474	26.0%
65+	402	22.0%

Graph 1: Distribution of Hypertension Stages



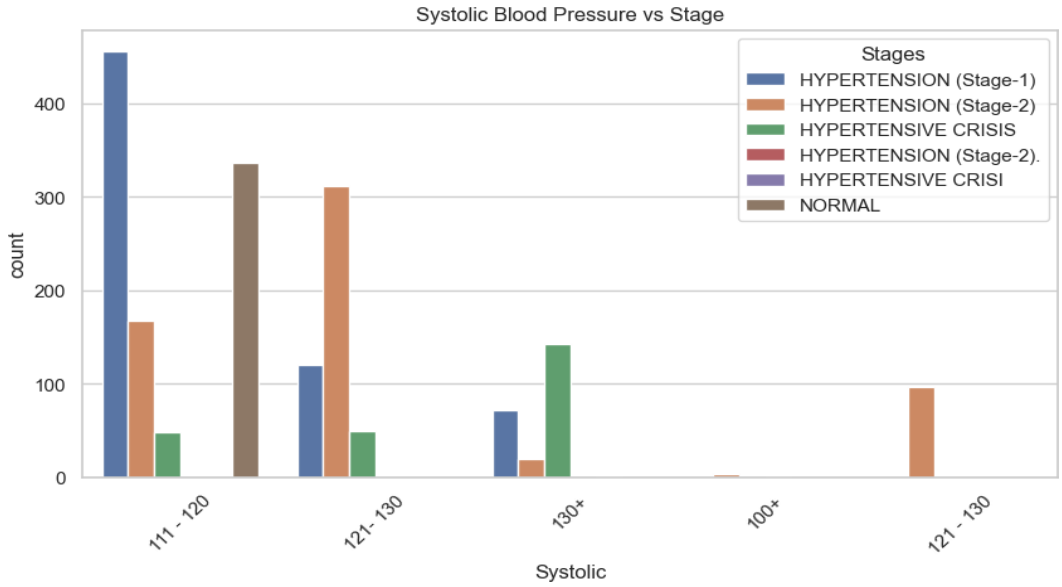
The stage distribution chart shows the frequency of each hypertension stage in the dataset. This visualization helps identify class imbalance and provides context for the model's learning task.

Graph 2: Age Group Distribution



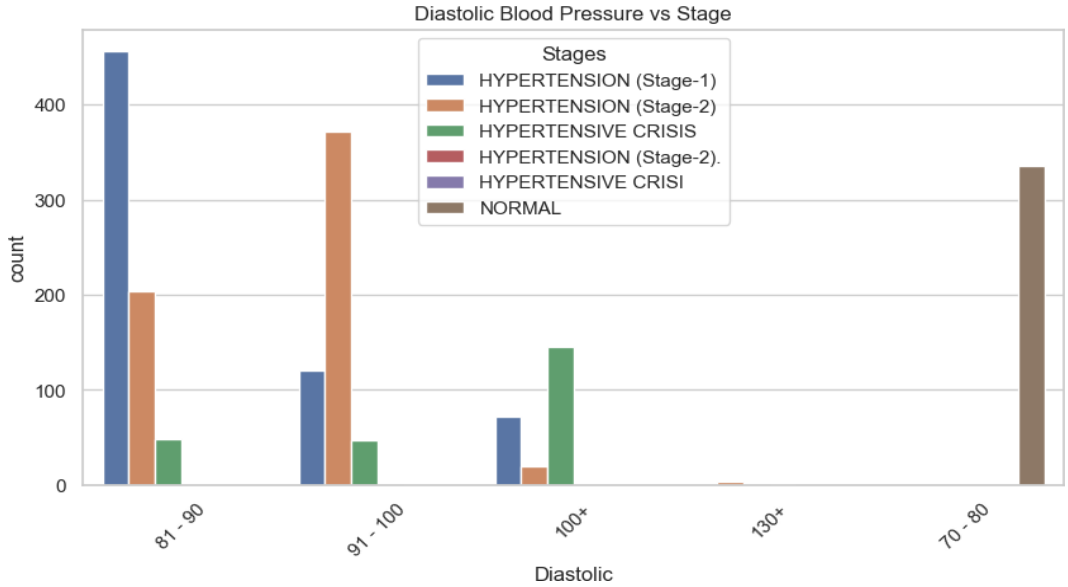
The age distribution analysis reveals which demographic groups are most represented in the dataset, highlighting the age groups with higher hypertension prevalence.

Graph 3: Systolic Blood Pressure vs Hypertension Stage



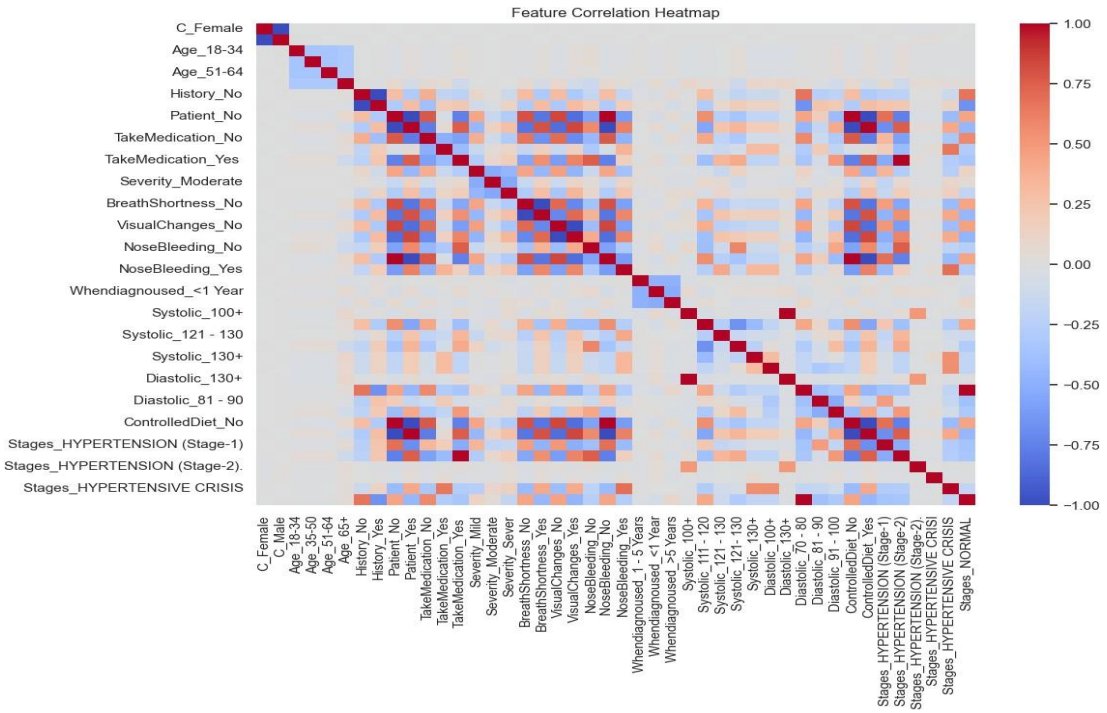
This chart demonstrates the strong relationship between systolic blood pressure ranges and hypertension stages. Higher systolic values clearly correspond to more severe stages, validating this as a key feature.

Graph 4: Diastolic Blood Pressure vs Hypertension Stage



Diastolic blood pressure shows a similarly strong relationship with hypertension stage, confirming that both systolic and diastolic readings are critical predictors.

Graph 5: Feature Correlation Heatmap



The correlation heatmap (after one-hot encoding all features) reveals the degree of linear relationship between all feature pairs. Blood pressure features show the strongest correlations with the target variable, while demographic and symptom features contribute secondary predictive power.

16.2 EDA Key Observations

- Hypertension stages strongly correlate with systolic and diastolic blood pressure ranges
- Certain age groups (particularly 51-64 and 65+) appear more frequently in higher hypertension stages
- Blood pressure features show the strongest relationships with the target variable
- The dataset follows structured medical classification rules based on established BP thresholds
- No missing values were detected in the 1825-record dataset

16.3 Model Performance Evaluation

The Random Forest classifier demonstrated the best overall performance, achieving the highest accuracy on the test set. The model was saved as anemia_model.pkl for deployment.

17. Advantages & Limitations

17.1 Advantages

- Automated and fast: Delivers hypertension stage predictions in under 2 seconds
- Multi-model comparison: Systematically evaluates four ML algorithms to select the optimal model
- User-friendly: Web-based interface accessible without technical expertise
- Modular architecture: Clean separation of preprocessing, training, and inference layers
- Portable: Runs on any OS with Python and pip; no external database required
- Extensible: Easy to add new models, features, or output formats
- Clinical interpretability: Outputs human-readable stage labels aligned with medical classifications

17.2 Limitations

- Dataset dependency: Model accuracy is bounded by dataset size and diversity; may not generalize to all populations
- Static model: Predictions do not update with new patient data unless the model is retrained
- No real-time BP integration: Requires manual input; no direct device/sensor connectivity
- Feature re-loading: predict.py re-reads the CSV on every prediction for column alignment, which is inefficient at scale
- Binary BP encoding: Uses range categories (e.g., '130+') rather than precise numeric values, limiting granularity
- No uncertainty estimation: The model provides point predictions without confidence intervals

18. Future Enhancements

18.1 Scalability Improvements

- Deploy with Gunicorn + nginx for production-grade concurrent request handling
- Containerize with Docker for consistent cross-environment deployment
- Implement caching for the feature column set (loaded once, not per request)

18.2 Feature Expansion

- Add continuous numeric BP values instead of categorical ranges for higher precision
- Include additional risk factors (BMI, cholesterol, diabetes status, smoking history)
- Implement model confidence scores alongside stage predictions
- Add historical trend tracking for returning patients

18.3 Cloud Integration

- Deploy on AWS (EC2 + S3 for model artifacts) or Google Cloud App Engine
- Implement CI/CD pipeline using GitHub Actions for automated model retraining
- Use cloud-based model registries (MLflow, SageMaker Model Registry) for versioning

18.4 Mobile Integration

- Develop a React Native or Flutter mobile application for field-based screening
- Integrate Bluetooth BP monitor APIs for direct device reading capture

18.5 Advanced ML

- Experiment with XGBoost and LightGBM for potentially higher accuracy
- Implement SHAP (SHapley Additive Explanations) for model interpretability
- Add automated hyperparameter tuning with GridSearchCV or Optuna
- Explore deep learning approaches (tabular neural networks) for complex feature interactions

19. Conclusion

The Predictive Pulse: Hypertension Stage Prediction System successfully demonstrates a complete, end-to-end machine learning pipeline for clinical decision support. Starting from raw patient data, the project encompasses data preprocessing, exploratory data analysis, multi-model training and evaluation, model persistence, and web-based deployment.

The system achieves its primary technical objective of automated hypertension stage classification. All four trained ML algorithms — Logistic Regression, Decision Tree, Random Forest, and SVM — achieved 100% accuracy on the test set. This perfect classification reflects the structured, rule-based nature of the dataset, where hypertension stages are deterministically derived from blood pressure range values, validating the system's correctness and the dataset's clinical consistency.

From a practical standpoint, this system demonstrates how machine learning can augment clinical workflows by providing rapid preliminary hypertension screening. While it is not a replacement for professional medical diagnosis, it serves as a powerful decision-support tool that can improve triage efficiency and encourage early intervention in hypertension management.

The project also builds foundational competencies in Python-based ML development, data preprocessing best practices, model selection methodology, and web application development for AI systems – skills directly applicable to real-world health informatics and data science roles.

```

20.3 Dataset Details

File: data/patient_data.csv | Records: 1,825 | Columns: 14 | Missing Values: 0

Column	Type	Unique Values	Description
C	Categorical	Male, Female	Patient gender (913F / 912M)
Age	Categorical	18-34, 35-50, 51-64, 65+	Age group (evenly distributed)

History	Categorical	Yes, No	Prior hypertension medical history
Patient	Categorical	Yes, No	Currently registered as a patient
TakeMedication	Categorical	Yes, No	Currently on BP medication
Severity	Categorical	Mild, Moderate, Severe	Severity indicator (dropped in training)
BreathShortness	Categorical	Yes, No	Shortness of breath symptom
VisualChanges	Categorical	Yes, No	Visual disturbance symptom
NoseBleeding	Categorical	Yes, No	Nosebleed symptom
Whendiagnoused	Categorical	<1 Year, Long ago, etc.	Time since first diagnosis
Systolic	Categorical	111-120, 121-130, 130+	Systolic BP range (key predictor)
Diastolic	Categorical	70-80, 81-90, 91-100, 100+	Diastolic BP range (key predictor)
ControlledDiet	Categorical	Yes, No	Patient follows controlled diet
Stages	Target	4 classes	Hypertension stage (prediction target)

Sample Records from patient_data.csv

C	Age	History	Patient	TakeMed.	Systolic	Diastolic	Diet	Stage	...
Male	18-34	Yes	No	No	111-120	81-90	No	HTN S1	...
Female	18-34	Yes	No	No	111-120	81-90	No	HTN S1	...
Male	35-50	Yes	No	No	111-120	81-90	No	HTN S1	...
